Solutions to Experimental Problem 1

Paper transistor

(Elvira Fortunato, Luís Pereira, Rui Igreja, Paul Grey, Inês Cunha, Diana Gaspar, Rodrigo Martins)

July 23, 2018

v1.4

Sketch of the solutions:**Part A. Circuit dimensioning (2.4 points)****A.1**

Using Ohm's law, the current through the voltage divisor is $I = V_{\text{in}}/(R_x + R_y)$, and $V_{\text{out}} = R_y I$. Thus

A.1

0.2pt

$$V_{\text{out}} = V_{\text{in}} \frac{R_y}{R_x + R_y}$$

A.2**A.2** Uncertainty in each measurement: $\pm 0.01 \Omega$

0.5pt

| # | R_{T1} | R_{T2} | R_{T3} |
|------------|----------|----------|----------|
| 1 | 122.3 | 125.3 | 125.3 |
| 2 | 122.3 | 125.4 | 125.4 |
| 3 | 122.3 | 125.3 | 125.4 |
| 4 | 122.2 | 125.2 | 125.5 |
| 5 | 122.3 | 125.4 | 125.4 |

A.3

- A.3** For a parallelepiped conductor of length l , width w and thickness t , the resistance is given by 0.3pt

$$R = \rho \frac{l}{wt}$$

For a thin film of square shape, $l = w$, thus

$$R = \rho \frac{l}{tw} = \frac{\rho}{t} = R_{\square}.$$

A.4

The weighted average value (weighed by $1/\sigma^2$) of the sheet resistance is $\bar{R} = 123.94 \pm 0.04 \Omega$ and $\rho = R_{\square} t$.

- A.4** $\bar{R} = 123.94 \pm 0.04 \Omega$ 0.4pt
 $\rho = 2.5 \pm 0.1 \times 10^{-3} \Omega \text{ m.}$

A.5

- A.5** For a rectangular thin film $R = R_{\square} \frac{l}{w}$, thus 0.5pt

$$R_1 = R_2 = R_{\square} (1 + 1/0.9 + 1/0.8 + 1/0.7 + 1/0.6 + 1/0.5 + 1/0.4 + 1/0.3) = 14.2897 R_{\square}$$

Measured values:

$$R_1 = 1776 \pm 1 \Omega \quad k_1 = 14.33$$

$$R_2 = 1787 \pm 1 \Omega \quad k_2 = 14.42$$

$$\bar{R} = 14.3 \pm 0.1$$

Comparison with the theoretical value: the average value is compatible, within the assigned error bar, with the theoretical value.

| V | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

B.3

The unloaded voltage is

$$V_{\text{out}} = V_{\text{in}} \frac{R_y}{R_x + R_y}$$

and the loaded voltage is

$$V_{\text{out}}^L = V_{\text{in}} \frac{R'_y}{R_x + R'_y},$$

where R'_y is the equivalent resistance of the parallel association between R_y and R_L :

$$R'_y = \frac{R_y R_L}{R_y + R_L}.$$

Thus,

$$f = \frac{\frac{R'_y}{R_x + R'_y}}{\frac{R_y}{R_x + R_y}} = \frac{(R_x + R_y)R'_y}{(R_x + R'_y)R_y} = \frac{(R_x + R_y)\frac{R_L}{R_y + R_L}}{R_x + R_y \frac{R_L}{R_y + R_L}}$$

Note that in terms of $\eta = 1/(1 + \frac{R_y}{R_L})$, the factor f can be written as

$$f = \frac{(R_x + R_y)\eta}{R_x + R_y\eta}$$

Confidential

When $R_L \gg R_y$, $\eta \rightarrow 1$, and $f \rightarrow 1$; when $R_L \ll R_y$, $\eta \rightarrow 0$ and $f \rightarrow 0$.

B.3

$$f = \frac{(R_x + R_y)\eta}{R_x + R_y\eta}$$

B.5**B.5** Output curves:

0.5pt

**Confidential****B.6**

The R_{DS} values are obtained from the slopes of the linear region of the output curves (small V_{DS} voltages).

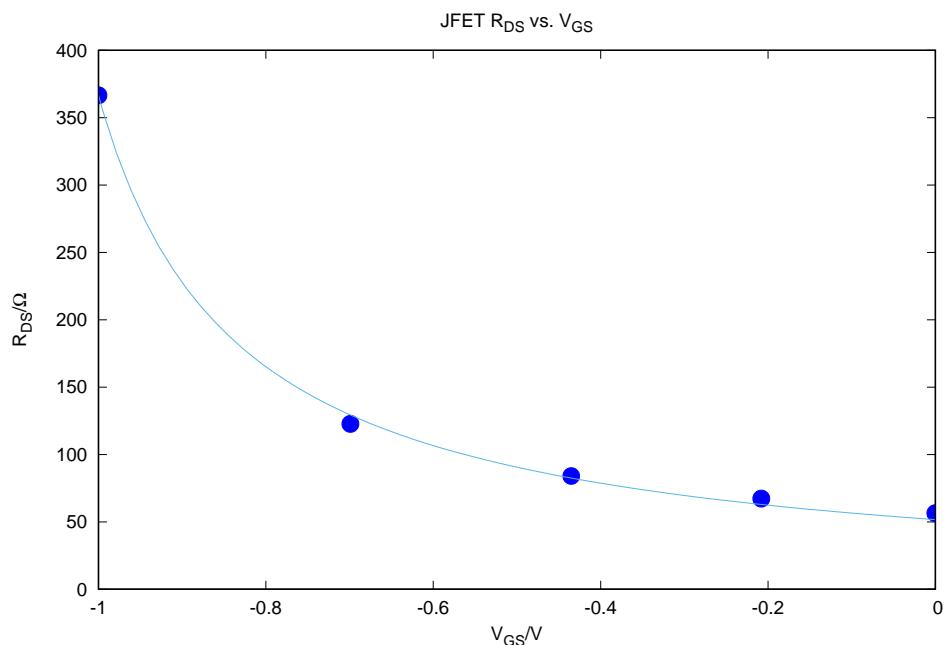

The last point in the plot $R_{DS}(V_{GS})$ has a large error bars as we are missing points in the linear regime, and will be ignored.

The solid line in the plot is the result of a fit to $R_{DS} = R_{DS}^0 (1 - V_{GS}/V_P)$, that gave $R_{DS}^0 = 52(2) \Omega$, $V_P = -1.18(1) \text{ V}$.

B.7

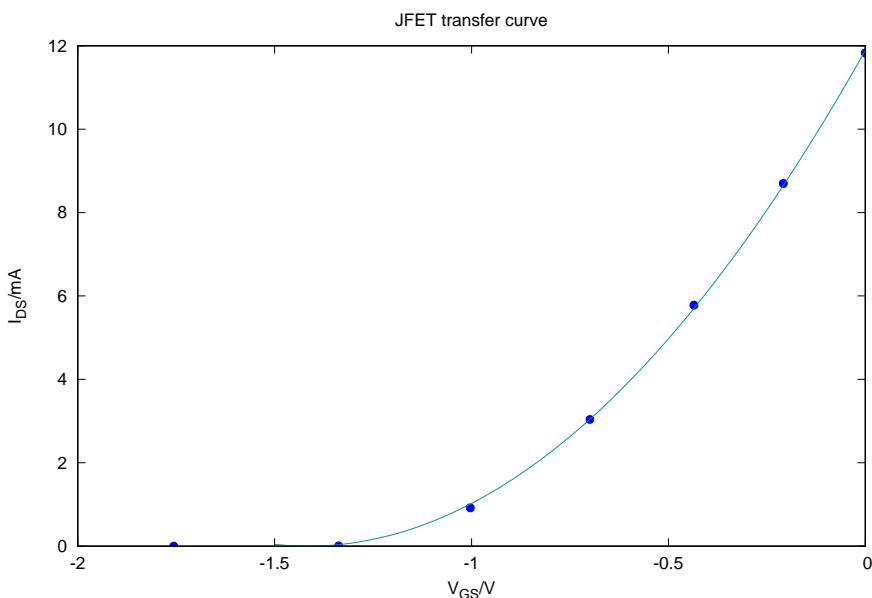

The data was obtained with $V_{DS} = +3$ V. The solid line is the result of the fit to the data of the function

$$I_{DS} = I_{DSS} (1 - V_{GS}/V_P)^2.$$

The fitted parameters are $I_{DSS} = 11.89 \pm 0.06$ mA and $V_P = -1.42 \pm 0.02$ V.

B.7

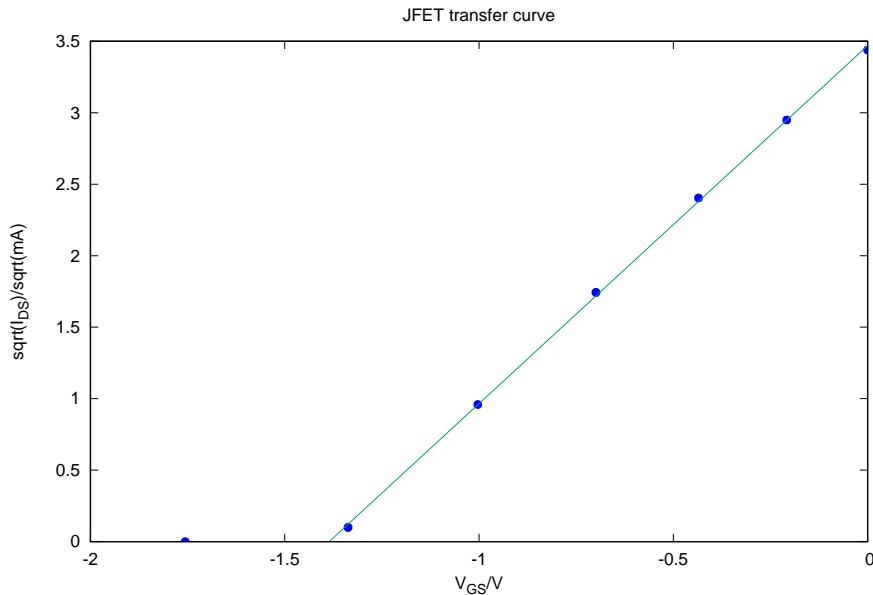

0.3pt

**Confidential****B.8**

From

$$I_{DS} = I_{DSS} (1 - V_{GS}/V_P)^2$$

a plot of $\sqrt{I_{DS}}$ as function of V_{GS} should yield a straight line with slope $a = -\sqrt{I_{DS}}/V_P$ that intercepts the x -axis at V_P .

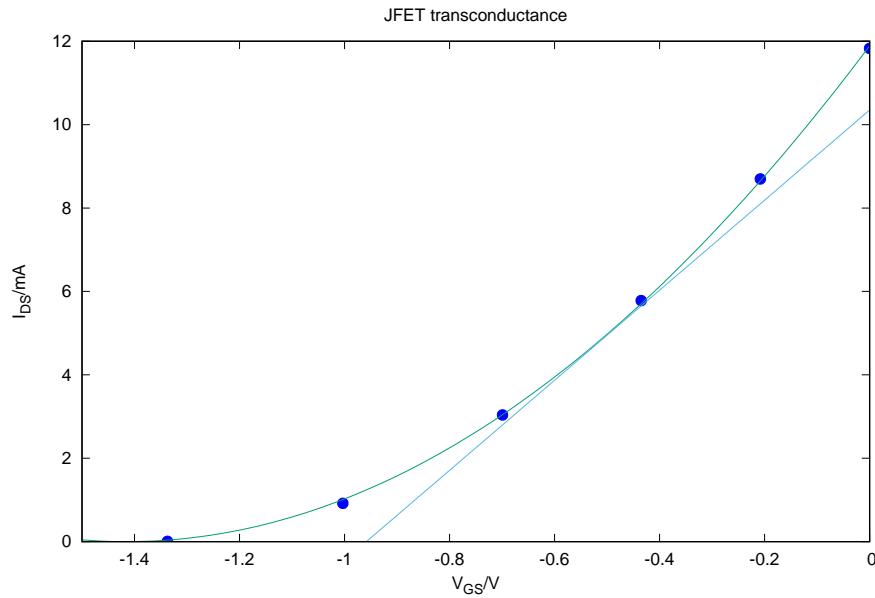

A linear fit to $f(x) = ax + b$ gave $a = 2.50(2)$ and $b = 3.47(2)$. Thus, $V_P = -b/a = -1.39(2)$ V and $I_{DSS} = 4.23^2 = 12.0(2)$ mA.

| | | |
|------------|---|-------|
| B.8 | $V_P = -b/a = -1.39(2)$ V $I_{DSS} = 4.23^2 = 12.0(2)$ mA. | 0.4pt |

B.9

The transconductance is the slope of the transfer curve at a given point. From the transfer plot, we draw the tangent at the point with abscissa -0.50 V and read the slope from the graph, obtaining $g = 10.8(1)$ m m^{-1} .

From

$$I_D = I_{DSS} (1 - V_{GS}/V_P)^2,$$

$$g = \frac{\partial I_D}{\partial V_{GS}} = 2I_{DSS} (1 - V_{GS}/V_P) \left(-\frac{1}{V_P} \right) = \frac{2I_{DSS}}{V_P} (V_{GS}/V_P - 1).$$

Substituting values,

$$g = 10.8 \text{ m}^{-1}$$

a value that agrees with that obtained using the graphical method.

C.2

The data is similar to that of the charge of a capacitor, superimposed with an almost linear component that corresponds to the charge of the second capacitor with a larger time constant.

A least squares fit to a $A(1 - \exp(-t/\tau_1)) + B(1 - \exp(-t/\tau_2))$ is also depicted, showing that the data can be well fitted by this model. The shorter time constant is $\tau_1 = 43(8)$ s, the longer time constant, τ_2 is roughly 20 times larger.

Confidential

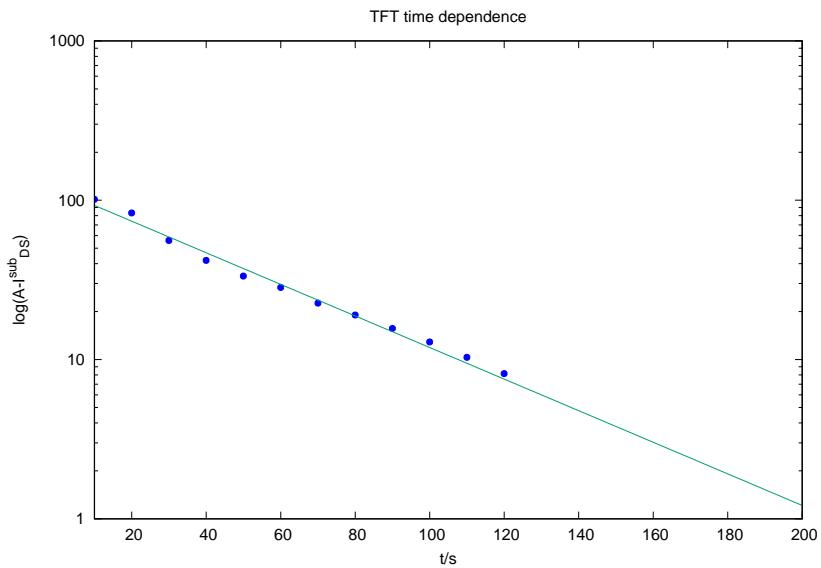

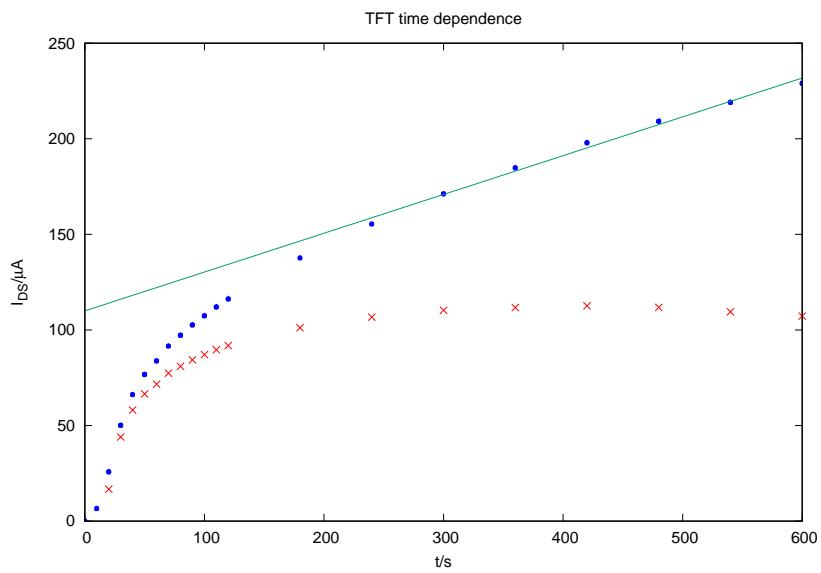

Let $I_{DS}^{\text{sub}} = A(1 - \exp(-t/\tau_1))$ be the data subtracted from the long time constant component. A logarithmic plot of $\log(A - I_{DS}^{\text{sub}})$ should be a straight line of slope $-1/\tau_1$. The constant A , the saturation current of the short τ_1 component, can be easily estimated from the above plot.

The slope of the line is $m = -0.023(1)$, from which we get $\tau_1 = 44(3)$ s. The error bar is underestimated, as it does not take into account the error in the subtraction of the τ_2 component.
